October, 2002

One important need for local hurricane emergency planning is current data about the population of communities in the areas at risk. Data to meet this need were produced by accessing 2000 Census files for each of the 22 counties on the Texas Gulf coast. For each county, GIS analysts imported data on the population of each census tract, the boundaries of those census tracts, the boundaries of the incorporated jurisdictions within each county, and the boundaries of each of the five risk areas. The data were then analyzed to determine the current population for each jurisdiction in each risk area. The data for each county were analyzed to compute the total population for all jurisdictions within each risk area.

Estimates of the number of tourist rooms are also important because they can be a significant source of additional evacuation vehicles. Data to meet this need were produced by searching the web sites for the tourism bureau in each of the 22 coastal counties to obtain information on the total number of hotel/motel rooms and the occupancy rate, by month, for the 2001 calendar year. Unfortunately, room occupancy data are reported by quarter, so the tables below report room occupancies during the summer months (June, July, and August) are taken from third quarter (July, August, and September). Similarly, room occupancy during the fall months (September, October, and November) are taken from fourth quarter (October, November, and December).

Another limitation of these tables is that there are no data to indicate what is the average number of persons occupying each room. It will normally be the case that some rooms will be occupied by single individuals (e.g., on business trips), whereas other rooms will have multiple occupancy (e.g., families on vacations). As a very rough (and conservative) approximation, the total number of tourists was estimated from room occupancy by multiplying the latter figure by three persons per room.

Finally, there is no source for tourist data that is disaggregated below the county level. Thus, it is not possible to estimate the number of hotel/motel rooms in each jurisdiction within a county, let alone to estimate the number in each risk area within a jurisdiction. Thus, the number of rooms is reported only for the county. However, this does not appear to be a major limitation because it is likely that all tourists in a county will evacuate when warned of an approaching hurricane, regardless of what risk area their accommodations are located in. This is the assumption that was made in calculating current evacuation time estimates for the Texas Gulf coast (Lindell, Prater, and Wu, 2002). Under this quite plausible assumption, the absence of tourist data disaggregated below the county level makes little difference in any operational decision during a hurricane emergency. For reporting purposes, the data for all tourists are assigned to Risk Area 1.

The number of evacuees was computed from the community population data by multiplying the number of persons in each risk area of each community by the proportion of persons expecting to evacuate from that risk area at each of the five hurricane categories. These data, which were previously reported by Lindell, Prater, Perry, and Wu (2002) are presented in Table A below.

Table A: Smoothed percentages of households expecting to evacuate for hurricanes in Category 1 through Category 5, by Risk Area.

Risk Area	Category One	Category Two	Category Three	Category Four	Category Five
1	45.9	63.7	87.8	98.2	100.0
2	35.9	53.7	77.8	88.2	91.4
3	31.1	48.9	73.0	83.4	86.6
4	28.2	46.0	70.1	80.5	83.7
5	26.5	44.3	68.4	78.8	82.0

The number of evacuating households was computed by dividing the estimated number of evacuees by 2.73, which was the average number of persons per household reported in Lindell, Prater, Sanderson, Lee, Zhang, Mohite and Hwang (2001). The number of evacuating vehicles was computed by multiplying the number of households by 1.62, which was the number of evacuating vehicles per household reported by Lindell, et al. (2001). As noted above, the number of tourists per room was assumed to be 3.0 and the number of evacuating tourist vehicles per household was assumed to be 1.0.

The results of the population and evacuation analyses are presented in six sets of tables. The first set of tables contains *local population data* for each study area, with study areas listed from North to South, and counties organized alphabetically within study areas. The remaining five sets of tables contain the *evacuating population* data for each hurricane category. As with the local population data, study areas are ordered from North to South, and counties are organized alphabetically within study areas. An index to these tables is located on pages 7 and 8.

Another issue that must be addressed in assessing evacuation needs is the percentage of each county's population that has a mobility or self-care limitation that would require assistance. Table B presents the relevant data, by county and age group, from the 2000 census.

Table B: Percent of Population with Mobility or Self-Care Limitation

\* Data from 2000 US Census, Table DP-2, Profile of Selected Social Characteristics: Population with a Disability

It is important to note that these data include all disabilities, so they certainly overestimate the proportion of the population that would require assistance in a hurricane. Prater and Lindell (2002) indicated that precise estimates are not available for the number of people needing transportation, it is clear that. Only ten of the 22 EMCs in evacuation counties could supply numerical estimates of their transit dependent populations and several of these mentioned getting their data from the presentations on the DEM website. However, all of these EMCs expected that the number of transit dependent evacuees would be quite low. They also expected most people to have friends or relatives who will pick them up in case they need to evacuate, which is consistent with the findings from research on past disasters. These reports by practitioners are consistent with the findings of disaster researchers (Drabek, 1986; Lindell & Perry, 1992; Tierney, Lindell & Perry, 2001).

These data are further supported by data from a survey of the disabled, elderly, and low income populations in 78 Texas counties that was conducted by the Office of Community Transportation Services of the Texas Health and Human Services Commission (Spanhel, 1998). Selected results of this survey are shown in Table C.

Table C: Data from *Transportation Needs Survey*

Population Segment	% Owning Car or Truck	% Of Those Whose Vehicle is in Good Working Order	% Of Those Not Owning Car or Truck That Have Access to Car or Truck
Disabled	64%	90%	41%
Elderly	68%	87%	10%
Low Income	36%	65%	47%

These data show that different segments of the population vary in their evacuation needs. The majority of the *Disabled* population surveyed own a car or truck, most of these have vehicles in good working order, and a high percentage of those that do not own a vehicle have access to one. An even larger percentage of the *Elderly* own their own car or truck, and most of these vehicles are in good working order. However, few of the *Elderly* who do not own a vehicle have access to one. Finally, the *Low Income* group is least likely to own a vehicle and also is least likely to own one in good working order, but a high percentage have access to someone else's vehicle. Local emergency managers should therefore target low income and elderly populations to make sure all who need to evacuate have means of transportation.
